## **Executive Summary**

The UK Government published its strategic policy framework for air quality management in 1995 establishing national strategies and policies on air quality. The NI Environment Order came into operation in January 2003 and implements both the European Air Framework Directive 96/62EC and the UK Air Quality Strategy. The Air Quality Strategy provides a framework for air quality control through air quality management and air quality standards. New national air quality standards have been proposed by the Expert Panel on Air Quality Standards (EPAOS) for the UK.

All local authorities are thus required to undertake an air quality review. In areas where air quality objectives are not anticipated to be met by the specified date, Local Authorities are required to establish Air Quality Management Areas to improve air quality.

The Local Air Quality Management Policy Guidance (LAQM.PGNI (03)) is designed to help relevant authorities with their local air quality management duties under Part III of the environment (NI) Order 2002. The guidance sets out the legislative framework for the system of Local Air Quality Management (LAQM). The Environment (NI) Order 2002 provides the framework for LAQM across Northern Ireland.

The Air Quality Objectives set out in the Air Quality Regulations (NI) 2003 provide the statutory basis for the system of LAQM. The first step in this process is to undertake a review of current and potential future air quality. The number of reviews necessary depends on the likelihood of achieving the objectives.

This report on domestic fuel combustion forms part of the stage three air quality review for Larne Borough Council. Only  $PM_{10}$  and sulphur dioxide are considered in this report. This is because  $PM_{10}$  and sulphur dioxide are the only pollutants of concern when considering domestic fuel combustion. This report investigates  $PM_{10}$  and sulphur dioxide levels through an examination of the location and size of domestic combustion sources, emissions modelling exercises and by reference to monitored air quality data.

As part of this report, detailed modelling using ADMS version 3.1 has been undertaken at three one kilometre square grids identified in the Stage 2 assessment. These are:

- Craigy Hill
- Antiville
- Town Parks

As the grids are adjacent they have been modelled together as the emissions from each grid will impact on the concentrations of the adjacent grid. The model results have been bias corrected using data from Rosebrook Avenue in Carrickfergus, this is necessary because there is no continuous monitoring at present of  $SO_2$  and  $PM_{10}$  in a location suitable for model verification residential area in Larne. Carrying out monitoring at a relevant location would mean a local bias adjustment factor for the model could be calculated and the model adjusted accordingly. This would subsequently provide greater certainty and confidence in the modelled results. Such data could also be used in further rounds of assessment to further verify the model output. This modelling study carried out within this report is intended to provide indicative results and will alert Larne Borough Council if concentrations in the district are likely to exceed the objectives.

### Particulates (PM<sub>10</sub>)

The modelling results suggest that there will not be an exceedence, of the 90.4 percentile daily mean  $PM_{10}$  objective in 2004. This is the most stringent of the PM10 objectives. If this objective is met then it is likely that the annual mean objective in 2004 will also be met. It is recommended that no further assessment be carried out for this source.

### Sulphur dioxide (SO<sub>2</sub>)

The modelling results suggest that there will not be an exceedence of the 15 minute mean  $SO_2$  objective. This is the most stringent  $SO_2$  objective and so it is likely that the hourly and daily  $SO_2$  objectives will also be met. It is recommended that no further assessment be carried out for this source.

### Appendix 1 Carrickfergus ambient air monitoring programme

### 1 Introduction

### 1.1 PURPOSE OF THE STUDY

Netcen was commissioned to complete the domestic fuel combustion section of the third stage review and assessment for Larne Borough Council.

### 1.2 GENERAL APPROACH TAKEN

The approach taken in this study was to:

- Collect and interpret additional data to support the third stage assessment, including detailed fuel use survey data for locations where exceedences were predicted;
- Use the monitoring data from a monitoring station in Carrickfergus to assess the ambient concentrations produced by domestic fuel combustion and to validate the output of the modelling studies. Data from Carrickfergus was used because no monitoring data from Larne was available;
- Model the concentrations of PM<sub>10</sub> and SO<sub>2</sub> in the selected grid squares, concentrating on the locations (receptors) where people might be exposed over the relevant averaging times of the air quality objectives;
- Present the concentrations as contour plots of concentrations.

### 1.3 VERSION OF THE POLLUTANT SPECIFIC GUIDANCE USED IN THIS ASSESSMENT

This report has used the guidance in LAQM.TG(03), published in February 2003.

### 1.4 NUMBERING OF FIGURES AND TABLES

The numbering scheme is not sequential, and the figures and tables are numbered according to the chapter and section that they relate to.

### 1.5 UNITS OF CONCENTRATION

The units throughout this report are presented in  $\mu g$  m<sup>-3</sup> (which is consistent with the presentation of the new AQS objectives), unless otherwise noted.

### 1.6 STRUCTURE OF THE REPORT

This document is a Third Stage Air Quality review for Larne Borough Council for  $PM_{10}$  and  $SO_2$  from domestic fuel combustion. This chapter, Chapter 1 has summarised the approach to completing the study.

Chapter 2 of the report describes the most recent developments in the UK's Air Quality Strategy (AQS). In addition, it discusses when implementation of an AQMA is required.

Chapter 3 contains details of the information used to conduct the stage 3 review and assessment for Larne Borough Council.

Chapters 4 and 5 describe the review and assessment standards for the two relevant pollutants,  $SO_2$  and  $PM_{10}$  and the monitoring data used for these pollutants.

Chapter 6 presents the fuel use survey results.

Chapter 7 presents the detailed modelling. The results of this analysis are displayed as contour plots.

## 2 The updated Air Quality Strategy

### 2.1 THE NEED FOR AN AIR QUALITY STRATEGY

After agreement of a Common Position on the Air Quality Daughter Directives (AQDD), in June 1998 at the European Union Environment Council, the government published its proposals for review of the National Air Quality Strategy (in 1999). Subsequently the Air Quality Strategy for England, Scotland, Wales and Northern Ireland was published in January 2000.

The NI Environment Order came into operation in January 2003 and implements both the European Air Framework Directive 96/62EC and the UK Air Quality Strategy. The Expert Panel on Air Quality Standards (EPAQS) has proposed new national air quality standards for the UK.

The NI Environment Order 2002 provides the framework for LAs to review air quality and for implementation of an AQMA. It is issued by the Department of the Environment in Northern Ireland under Article 16 of the Environment (NI) Order 2002. Under article 16 of the order, District Councils and other relevant authorities are required to have regard to this guidance when carrying out any of their duties under, or by virtue of Part III of the order. The guidance the document sets out is outlined in Table 2.1 below.

#### Table 2.1: NI Environment Order 2002 key Guidance

- The statutory background and the legislative framework within which relevant authorities have to work
- The new principles behind reviews and assessments of air quality up to 2010 and the recommended steps that relevant authorities should take
- The timetable for reviews and assessments up to 2010
- How district councils should handle the designation of AQMAs
- How relevant authorities should handle the drawing up and implementation of action plans
- Recommendations and suggestions on taking forward the development of local and regional air quality strategies
- Suggestions of how relevant authorities should consult and liase with others
- Local transport measures which Roads Service might wish to consider
- The general principles behind air quality and land use planning; and
- How enforcing authorities should use powers of entry under Article 19 of the Order

## 2.2 OVERVIEW OF PRINCIPLES AND MAIN ELEMENTS OF THE NATIONAL AIR QUALITY STRATEGY

The main elements of the AQS can be summarised as follows:

- The use of a health effects based approach using national air quality standards and objectives.
- The use of policies by which the objectives can be achieved and which include the input of important actors such as industry, transportation bodies and local authorities.
- The predetermination of timescales with target dates of 2003, 2004, 2005, 2008 and 2010 for the achievement of objectives and a commitment to review the Strategy every three years.

It is intended that the AQS will provide a framework for the improvement of air quality that is both clear and workable. In order to achieve this, the Strategy is based on several principles which include:

- the provision of a statement of the Government's general aims regarding air quality;
- · clear and measurable targets;
- a balance between local and national action and
- a transparent and flexible framework.

Co-operation and participation by different economic and governmental sectors is also encouraged within the context of existing and potential future international policy commitments.

### 2.2.1 National Air Quality Strategy

At the centre of the AQS is the use of national air quality standards to enable air quality to be measured and assessed. These also provide the means by which objectives and timescales for the achievement of objectives can be set. Most of the proposed standards have been based on the available information concerning the health effects resulting from different ambient concentrations of selected pollutants and are the consensus view of medical experts on the Expert Panel on Air Quality Standards (EPAQS). These standards and associated specific objectives to be achieved between 2003 and 2010 are shown in Table 2.2. The table shows the standards in  $\mu g m^{-3}$  with the number of exceedences that are permitted (where applicable).

Specific objectives relate either to achieving the full standard or, where use has been made of a short averaging period, objectives are sometimes expressed in terms of percentile compliance. The use of percentiles means that a limited number of exceedences of the air quality standard over a particular timescale, usually a year, are permitted. This is to account for unusual meteorological conditions or particular events such as November 5th. For example, if an objective is to be complied with at the 99.9th percentile, then 99.9% of measurements at each location must be at or below the level specified.

Table 2.2: Proposed Objectives included in the Air Quality Regulations (NI) 2003 for the purpose of Local Air Quality Management

Pollutant	Air Quality Objective		Date to be achieved by	
	Concentration	Measured as		
Benzene	16.25 μg m <sup>-3</sup>	Running annual mean	31.12.2003	
	3.25 μg m <sup>-3</sup>	Running annual mean	31.12.2010	
1,3 Butadiene	2.25 μg m <sup>-3</sup>	Running annual mean	31.12.2003	
Carbon Monoxide	10.0 mg m <sup>-3</sup>	Maximum daily running 8-hour mean	31.12.2003	
Lead	0.5 μg m <sup>-3</sup>	Annual mean	31.12.2004	
	0.25 μg m <sup>-3</sup>	Annual mean	31.12.2008	
Nitrogen Dioxide <sup>1</sup>	200 μg m <sup>-3</sup> not to be exceeded more than 18 times a year	1 hour mean	31.12.2005	
	40 μg m <sup>-3</sup>	annual mean	31.12.2005	
Particles (PM <sub>10</sub> ) <sup>2</sup>	50 μg m <sup>-3</sup> not to be exceeded more than 35	24 hour mean	31.12.2004	
Gravimetric <sup>3</sup>	times a year			
	40 μg m <sup>-3</sup>	annual mean	31.12.2004	
Sulphur Dioxide	350 µg m <sup>-3</sup> not to be exceeded more than 24 times per year	1 hour mean	31.12.2004	
	125 μg m <sup>-3</sup> not to be exceeded more than 3 times per year	24 hour mean	31.12.2004	
	266 μg m <sup>-3</sup> not to be exceeded more than 35 times per year	15 minute mean	31.12.2005	

Notes

1	The objectives for nitrogen dioxide are provisional.
2	There are likely to be new particles objectives for 2010, not in regulation at present, expected after the
	review of the EU's first Air Quality Daughter Directive (2004).
3	Measured using the European gravimetric transfer standard or equivalent.

## 2.2.2 Relationship between the UK National Air Quality Standards and EU air quality Limit Values

As a member state of the EU, the UK must comply with European Union Directives.

There are three EU ambient air quality directives that the UK has transposed in to UK law. These are:

- **96/62/EC** Council Directive of 27 September 1996 on ambient air quality assessment and management. (the Ambient Air Framework Directive)
- **1999/30/EC** Council Directive of 22 April 1999 relating to limit values for sulphur dioxide, nitrogen dioxide, oxides of nitrogen, particulate matter and lead in ambient air. (the First Daughter Directive)
- **2000/69/EC** Directive of the European Parliament and the Council of 16 Nov 2000 relating to limit values for benzene and carbon monoxide in ambient air. (the Second Daughter Directive)

The first and second daughter directives contain air quality Limit Values for the pollutants that are listed in the framework directive. The United Kingdom (i.e. Great Britain and Northern Ireland) must comply with these Limit Values. The UK air quality strategy should allow the UK to comply with the EU Air Quality Daughter Directives, but the UK air quality strategy also includes some stricter national objectives for some pollutants, for example, sulphur dioxide.

The Government is ultimately responsibility for achieving the EU limit values. However, it is important that Local Air Quality Management is used as a tool to ensure that the necessary action is taken at local level to work towards achieving the EU limit values by the dates specified in those EU Directives.

### 2.2.3 Policies in place to allow these objectives to be achieved

The policy framework to allow these objectives to be achieved is one that that takes a local air quality management approach. This is superimposed upon existing national and international regulations in order to effectively tackle local air quality issues as well as issues relating to wider spatial scales. National and EC policies which already exist provide a good basis for progress towards the air quality objectives set for 2003 to 2010. For example, the Environmental Protection Act 1990 allows for the monitoring and control of emissions from industrial processes and various EC Directives have ensured that road transport emission and fuel standards are in place. These policies are being developed to include more stringent controls. Developments in the UK include the announcement by the Environment Agency in January 2000 on controls on emissions of SO<sub>2</sub> from coal and oil fired power stations. This system of controls means that by the end of 2005 coal and oil fired power stations will meet the air quality standards set out in the AQS. Northern Ireland now has in place the Air Quality Limit Value regulation (NI) 2002, the Air Quality (Amended) Limit Value Regulations (NI) 2002 and the Air Quality (Ozone) Regulations (NI) 2003. The Government has recognised the problems associated with achieving the standard for ozone, a secondary pollutant and transboundary in nature and it is recognised that local authorities themselves can exert little influence on concentrations when they are the result of regional primary emission patterns.

Local air quality management provides a strategic role for local authorities in response to particular air quality problems experienced at a local level. This builds upon current air quality control responsibilities and places an emphasis on bringing together issues relating to transport, waste, energy and planning in an integrated way. This integrated approach involves a number of different aspects. It includes the development of an appropriate local framework that allows air quality issues to be considered alongside other issues relating to polluting activity. It should also enable cooperation with and participation by the general public in addition to other transport, industrial and governmental authorities.

An important part of the Strategy is the requirement for local authorities to carry out air quality reviews and assessments of their area against which current and future compliance with air quality standards can be measured. Over the longer term, these will also enable the effects of policies to be studied and therefore help in the development of future policy. The Government has prepared guidance to help local authorities to use the most appropriate tools and methods for conducting a review and assessment of air quality in their Borough. This is part of a package of guidance being prepared to assist with the practicalities of implementing the AQS. Other guidance covers air quality and land use planning, air quality and traffic management and the development of local air quality action plans and strategies.

### 2.2.4 Timescales to achieve the objectives

In most local authorities, objectives will be met for most of the pollutants within the timescale of the objectives shown in Table 2.2. It is important to note that the objectives for NO<sub>2</sub> remain provisional.

### 2.3 AIR QUALITY REVIEWS

A range of Technical Guidance has been issued to enable air quality to be monitored, modelled, reviewed and assessed in an appropriate and consistent fashion. This includes the Technical Guidance LAQM.TG(03), and the previous version LAQM.TG4(00) May 2000, on 'Review and Assessment: Pollutant Specific Guidance'. This review and assessment has considered the procedures set out in the guidance.

The primary objective of undertaking a review of air quality is to identify any areas that are unlikely to meet national air quality objectives and ensure that air quality is considered in local authority decision making processes. The complexity and detail required in a review depends on the risk of failing to achieve air quality objectives.

At present Northern Ireland District Councils are engaged in the 3 staged approach of review and assessment. Stage 1 equates to an 'updating and Screening assessment', and a stage 2 and 3 equates to a 'detailed assessment'. The Stages are briefly described in Table 2.3. The latest technical guidance LAQM.TG(03) is based on a revised '2 step' approach. The Steps are briefly described in Table 2.3B.

The department recommends that district councils where feasible should use the latest technical guidance LAQM.TG(03) to complete their first rounds of review and assessment. Where District councils have commenced using the old technical guidance (LAQM. TG4 (00)) they may continue using the old guidance. However the methodology should be cross-referenced with the new guidance.

In the previous stages of review and assessment areas of potential exceedence of the air quality objectives for  $SO_2$  and  $PM_{10}$  were identified following LAQM.TG4 (00). The latest guidance, LAQM.TG (03) requires the assessment to be carried out in greater detail by considering 500x500m areas. The detailed modelling carried out in this Stage 3 uses the 1x1km areas, but this takes account of all areas of significant domestic solid fuel burning. In practice, the high resolution modelling and the method of source definition used in this report means that defining a 1x1km area makes no difference to the output when compared with a smaller total area. This is because treatment of the sources with the present model is at a fine resolution of 10-20m, hence the model output for a given location is the same whether the area modelled is a 1x1km area or a 0.5x0.5km area or even less.

Table 2.3: Brief details of Stages in the Air Quality Review and Assessment process

Stage	Objective	Approach	Outcome
First Stage Review and Assessment	Identify all significant pollutant sources within or outside of the authority's area.	Compile and collate a list of potentially significant pollution sources using the assessment criteria described in the Pollutant Specific Guidance	
	• Identify those pollutants where there is a <b>risk</b> of exceeding the air quality objectives, and for which further investigation is needed.	Identify sources requiring further investigation.	Decision about whether a Stage 2 Review and Assessment is needed for one or more pollutants. If not, no further review and assessment is necessary.
Second Stage Review and Assessment	<ul> <li>Further screening of significant sources to determine whether there is a significant risk of the air quality objectives being exceeded.</li> </ul>	Use of screening models or monitoring methods to assess whether there is a risk of exceeding the air quality objectives.	
	• Identify those pollutants where there is a <b>risk</b> of exceeding the objectives, and for which further investigation is needed.	The assessment need only consider those locations where the highest likely concentrations are expected, and where public exposure is relevant.	<ul> <li>Decision about whether a Stage 3 Review and Assessment is needed for one or more pollutants. If, as a result of estimations of ground level concentrations at suitable receptors, a local authority judges that there is no significant risk of not achieving an air quality objective, it can be confident that an Air Quality Management Area (AQMA) will not be required.</li> <li>However, if there is doubt that an air quality objective will be achieved a third stage review should be conducted.</li> </ul>

Table 2.3 (contd.): Brief details of Stages in the first Review and Assessment process

Stage	Objective	Approach	Outcome
Third Stage Review and Assessment	<ul> <li>Accurate and detailed assessment of both current and future air quality.</li> <li>Assess the likelihood of the air quality objectives being exceeded.</li> </ul>	Use of validated modelling and quality- assured monitoring methods to determine current and future pollutant concentrations.	
	Identify the geographical boundary of any exceedences, and description of those areas, if any, proposed to be designated as an AQMA.	The assessment will need to consider all locations where public exposure is relevant. For each pollutant of concern, it may be necessary to construct a detailed emissions inventory and model the extent, location and frequency of potential air quality exceedences.	<ul> <li>Determine the location of any necessary Air Quality Management Areas (AQMAs). Once an AQMA has been identified, there are further sets of requirements to be considered.</li> <li>A further assessment of air quality in the AQMA is required within 12 months which will enable the degree to which air quality objectives will not be met and the sources of pollution that contribute to this to be determined. A local authority must also prepare a written action plan for achievement of the air quality objective. Both air quality reviews and action plans are to be made publicly available.</li> </ul>

Table 2.3b: Brief details of Steps in the revised Air Quality Review and Assessment process

Level of Assessment	Objective	Approach
Updating and Screening Assessment (USA)	To identify those matters that have changed since the last review and assessment, which might lead to a risk of an air quality objective being exceeded.	<ul> <li>Use a checklist to identify significant changes that require further consideration.</li> <li>Where such changers are identified, then apply simple screening tools to decide whether there is sufficient risk of an exceedence of an objective to justify a detailed assessment.</li> </ul>
Detailed Assessment	To provide an accurate assessment of the likelihood of an air quality objective being exceeded at locations with relevant exposure. This should be sufficiently detailed to allow the designation or amendment of any necessary AQMAs.	Use quality-assured monitoring and validated modelling methods to determine current and future pollutant concentrations in areas where there is a significant risk of exceeding an air quality objective.

## 2.4 LOCATIONS THAT THE REVIEW AND ASSESSMENT MUST CONCENTRATE ON

For the purpose of review and assessment, the authority should focus their work on locations where members of the public are likely to be exposed over the averaging period of the objective. Table 2.4 summarises the locations where the objectives should and should not apply.

Table 2.4: Typical locations where the objectives should and should not apply

Averaging Period	Pollutants	Objectives should apply at	Objectives should not generally apply at
Annual mean	<ul> <li>1,3 Butadiene</li> <li>Benzene</li> <li>Lead</li> <li>Nitrogen dioxide</li> <li>Particulate Matter (PM<sub>10</sub>)</li> </ul>	All background locations where members of the public might be regularly exposed.	Building facades of offices or other places of work where members of the public do not have regular access.
		Building facades of residential properties, schools, hospitals, libraries etc.	Gardens of residential properties.
			• Kerbside sites (as opposed to locations at the building facade), or any other location where public exposure is expected to be short term
24 hour mean and 8-hour mean	<ul> <li>Carbon monoxide</li> <li>Particulate Matter (PM<sub>10</sub>)</li> <li>Sulphur dioxide</li> </ul>	All locations where the annual mean objective would apply.	Kerbside sites (as opposed to locations at the building facade), or any other location where public exposure is expected to be short term.
		Gardens of residential properties.	

Table 2.4 (contd.): Typical locations where the objectives should and should not apply

Averaging Period	Pollutants	Objectives should apply at	Objectives should generally not apply at
1 hour mean	<ul><li>Nitrogen dioxide</li><li>Sulphur dioxide</li></ul>	<ul> <li>All locations where the annual mean and 24 and 8-hour mean objectives apply.</li> </ul>	<ul> <li>Kerbside sites where the public would not be expected to have regular access.</li> </ul>
		<ul> <li>Kerbside sites (e.g. pavements of busy shopping streets).</li> </ul>	
		<ul> <li>Those parts of car parks and railway stations etc. which are not fully enclosed.</li> </ul>	
		Any outdoor locations to which the public might reasonably expected to have access.	
15 minute mean	Sulphur dioxide	All locations where members of the public might reasonably be exposed for a period of 15 minutes or longer.	

It is unnecessary to consider exceedences of the objectives at any location where public exposure over the relevant averaging period would be unrealistic, and the locations should represent non-occupational exposure.

### **Key Points**

- ♦ The Environment (Northern Ireland) Order 2002 has required the development of a National Air Quality Strategy for the control of air quality
- A central element in the Strategy is the use of air quality standards and associated objectives based on human health effects that have been included in the Air Quality Regulations.
- The Strategy uses a local air quality management approach in addition to existing national and international legislation. It promotes an integrated approach to air quality control by the various actors and agencies involved.
- Air quality objectives, with the exception of ozone, are to be achieved by specified dates up to the end
  of 2010.
- A number of air quality reviews are required in order to assess compliance with air quality objectives. The number of reviews necessary depends on the likelihood of achieving the objectives.

## 3 Information used to support this assessment

This Chapter presents the information used to support this review and assessment.

### 3.1 MAPS

Larne Borough Council provided detailed maps of each of the three  $1x1km^2$  areas of concern. The areas include areas of significant coal burning in the Borough.

All maps in this document are reproduced from Ordnance Survey material with permission of Her Majesty's Stationery Office © Crown Copyright. Unauthorised reproduction infringes Crown copyright and may lead to prosecution or civil proceedings.

### 3.2 METEOROLOGICAL DATA USED IN THE DISPERSION MODELLING

Hourly sequential data was obtained for 2002 for the Aldergrove site for input into the ADMS dispersion model.

### 3.3 AMBIENT MONITORING

At the time of modelling, Larne had not established any automatic monitoring in the area. Nearby, Carrickfergus Borough Council has undertaken automatic ambient air monitoring of  $SO_2$  and  $PM_{10}$  since July 2002. The instrumentation employed uses UV fluorescence for the measurement of  $SO_2$  and the TEOM technique for  $PM_{10}$ , these methods are appropriate for Detailed Assessment under LAQM (LAQM TG(03)). The monitoring station is located in Carrickfergus Town in Rosebrook Avenue. All TEOM data are quoted as mass equivalent according to the guidance.

Further monitoring information is provided in Appendix 1.

## 4 Review and Assessment for PM<sub>10</sub> from domestic fuel combustion

### 4.1 INTRODUCTION

Airborne particulate matter varies widely in its physical and chemical composition, source and particle size. Particles are often classed as either primary (those emitted directly into the atmosphere) or secondary (those formed or modified in the atmosphere from condensation and growth).  $PM_{10}$  particles (the fraction of particulates in air of very small size, <10  $\mu$ m aerodynamic diameter) can potentially pose significant health risks as they are small enough to penetrate deep into the lungs. Larger particles are not readily inhaled.

A major source of fine primary particles is combustion processes, in particular diesel combustion, where transport of hot exhaust vapour into a cooler tailpipe or stack can lead to spontaneous nucleation of "carbon" particles before emission. Secondary particles are typically formed when low volatility products are generated in the atmosphere, for example the oxidation of sulphur dioxide to sulphuric acid. The atmospheric lifetime of particulate matter is strongly related to particle size, but may be as long as 10 days for particles of about 1  $\mu m$  in diameter.

Concern about the potential health impacts of  $PM_{10}$  has increased very rapidly over recent years. Increasingly, attention has been turning towards monitoring the smaller particle fraction,  $PM_{2.5}$ , which is capable of penetrating deepest into the lungs, or to even smaller size fractions or total particle numbers.

### 4.2 LATEST STANDARDS AND OBJECTIVES FOR PM<sub>10</sub>

The government and the devolved administrations have adopted two air quality objectives for fine particles  $(PM_{10})$ , which are the equivalent to the EU Stage 1 limit values in the first Air Quality Daughter Directive. The gravimetric objectives are:

- An annual mean of 40 μg m<sup>-3</sup>.
- A 24 hour mean of 50  $\mu$ g m<sup>-3</sup> not to be exceeded more than 35 days per year.

The EU has also set indicative limit values for  $PM_{10}$  which are to be achieved by 1<sup>st</sup> January 2010. These stage 2 limit values are considerably more stringent and are:

- For England, Wales and Northern Ireland (except London), a 24 hour mean of 50 μg m<sup>-3</sup> not to be exceeded more than 7 days per year and an annual mean of 20 μg m<sup>-3</sup> to be achieved by the end of 2010;
- For London, a 24 hour mean of 50  $\mu g$  m<sup>-3</sup> not to be exceeded more than 10 days per year and an annual mean of 23  $\mu g$  m<sup>-3</sup> to be achieved by the end of 2010. An annual mean objective of 20  $\mu g$  m<sup>-3</sup> to be achieved by the end of 2015 has also been set.

The 24 hour objective is more stringent than the annual mean objective in 2004. However, the opposite is true in 2010, and the annual mean objective is more stringent than the 24 hour objective. However there is no requirement for local authorities to achieve the 2010 objectives.

### 4.3 THE NATIONAL PERSPECTIVE

National UK emissions of primary  $PM_{10}$  have been estimated as totalling 182,000 tonnes in 2001. Of this total, around 18% was derived from road transport sources, 11% from power stations and 21% from combustion in commercial and residential plant.

The Government established the Airborne Particles Expert Group (APEG) to advise on sources of  $PM_{10}$  in the UK and current and future ambient concentrations. Their conclusions were published in January 1999 (APEG, 1999). APEG concluded that a significant proportion of the current annual average  $PM_{10}$  is due to the secondary formation of particulate sulphates and nitrates, resulting from the oxidation of sulphur and nitrogen oxides. These are regional scale pollutants and the annual concentrations do not vary greatly over a scale of tens of

kilometres. There are also natural or semi-natural sources such as wind-blown dust and sea salt particles. The impact of local urban sources is superimposed on this regional background. Such local sources are generally responsible for winter episodes of hourly mean concentrations of  $PM_{10}$  above 100  $\mu g$  m<sup>-3</sup> associated with poor dispersion. However, it is clear that many of the sources of  $PM_{10}$  are outside the control of individual local authorities and the estimation of future concentrations of  $PM_{10}$  are in part dependent on predictions of the secondary particle component.

### 4.4 MONITORING DATA

 $PM_{10}$  concentrations have been continuously monitored in Carrickfergus since July 2002. The instrumentation employed uses the TEOM technique for  $PM_{10}$ , these methods are appropriate for Detailed Assessment under LAQM (LAQM TG(03)). The monitoring station is located in Carrickfergus Town in Rosebrook Avenue. The exact location of the monitoring station and more detail is provided in appendix 1. All the  $PM_{10}$  concentrations presented and used in this study are in gravimetric equivalents.

## 5 Review and Assessment for SO<sub>2</sub> from domestic fuel combustion

### 5.1 INTRODUCTION

Sulphur dioxide is a corrosive acid gas which combines with water vapour in the atmosphere to produce acid rain. Both wet and dry deposition have been implicated in the damage and destruction of vegetation and in the degradation of soils, building materials and watercourses.  $SO_2$  in ambient air is also associated with asthma and chronic bronchitis.

The principal source of this gas is power stations burning fossil fuels which contain sulphur. Episodes of high concentrations of  $SO_2$  now only tend to occur in cities in which coal is still widely used for domestic heating, in industry and in power stations. As most power stations are now located away from urban areas,  $SO_2$  emissions may affect air quality in both rural and urban areas. Since the decline in domestic coal burning in cities and in power stations overall,  $SO_2$  emissions have diminished steadily and, in most European countries, they are no longer considered to pose a significant threat to health.

### 5.2 LATEST STANDARDS AND OBJECTIVES FOR SO<sub>2</sub>

Two new objectives have been introduced for  $SO_2$  in the AQS based on the limit values in the Air Quality Daughter Directive. Hence there are now three objectives:

- 266  $\mu$ g m<sup>-3</sup> as a 15 minute mean (maximum of 35 exceedences a year or equivalent to the 99.9<sup>th</sup> percentile) to be achieved by the 31<sup>st</sup> December 2005
- $350~\mu g~m^{-3}$  as a 1 hour mean (maximum of 24 exceedences a year or equivalent to the  $99.7^{th}$  percentile) to be achieved by the  $31^{st}$  December 2004
- $125 \, \mu g \, m^{-3}$  as a 24 hour mean (maximum of 3 exceedences a year or equivalent to the  $99^{th}$  percentile) to be achieved by the  $31^{st}$  December 2004

The 15 minute mean objective is the most stringent; the other two objectives will not be exceeded if this objective is not exceeded.

### 5.3 THE NATIONAL PERSPECTIVE

Sulphur dioxide is emitted in the combustion of coal and oil. Emissions today are dominated by fossil fuelled power stations. Combustion in energy production accounted for 73% of the national total emission. Emissions from road transport are a very small fraction of the national total: less than 1% and combustion in Commercial, institutional and residential combustion accounted for 18% of the national total.

Exceedences of the 15-minute air quality standard currently occur near industrial processes for which the stack heights were designed to meet previous air quality standards and downwind of large combustion plant such as power stations. Exceedences are also possible in areas where significant quantities of coal are used for space heating. These large combustion plants are currently regulated under BATNEEC and the EPA 1990, and will come under the provisions of the IPPC. The government considers that bearing in mind the envisaged change in fuel use, it does not expect exceedences of the 15-minute objective by 2005 from these sources.

### 5.4 MONITORING DATA

Sulphur dioxide concentrations have been continuously monitored in Carrickfergus since July 2002. The instrumentation employed uses UV fluorescence for the measurement of  $SO_2$ , these methods are appropriate for Detailed Assessment under LAQM (LAQM TG(03)). The monitoring station is located in Carrickfergus Town in Rosebrook Avenue. The exact location of the monitoring station and further details are provided in Appendix 1.

## 6 Results of the fuel use survey

### 6.1 INTRODUCTION

Larne Borough Council carried out a domestic fuel use survey for three areas identified in the Stage 2 Review and Assessment as requiring modelling, Craigy Hill, Antiville and Town Parks. The study supplied data for the modelling.

The survey determined:

- The types and quantities of fuels used in the domestic sector
- Seasonal use of heating fuels
- The types of heating appliances used
- Any proposed change in fuel usage
- The total number of houses that burn coal in each of the survey areas.

The survey sampled the following percentage of properties in each area:

Table 6.1: Estimated number of houses surveyed

Survey Area	Total number of houses	Number of houses surveyed	%
Craigy Hill	1537	291	19
Antiville	1163	292	25
Town Parks	1461	319	22

### 6.2 LARNE SURVEY RESULTS

As the three 1km² areas to be assessed were adjacent, the emissions sourced from each grid could potentially impact on the pollutant concentrations in the adjacent grid, i.e. emissions from Antiville would effect the pollutant concentrations in Craigy Hill when the meteorological conditions were right. Thus modelling the areas separately may lead to underestimation of the actual concentrations. Therefore, it was determined that the three grids should be modelled as one larger grid area, therefore from here on when referring to 'the grid', it is meant 'the area containing Craigy Hill, Antiville and Town Parks'. In practice the modelling therefore is better able to account for pollutant contribution from a wider area. Although this does slightly reduce the capability of the model to account for the spatial pattern of housing, it does not affect the resolution of the modelling. The results of the fuel use surveys are shown below by area, but were aggregated for model running purposes.

The results from each survey area showed that oil was the most popular main fuel for heating and solid fuel was the second most popular primary fuel (Table 6.2).

Table 6.2: Primary fuel breakdown by survey area (%)

Survey Area	Oil	Solid Fuel
Craigy Hill	65	8
Antiville	54	26
Town Parks	58	26

The majority of homes in each of the surveyed areas do not rely on any other fuel types for back-up or occasional heating, in those that do solid fuel is the main secondary fuel source, followed by electricity. Only one house surveyed used oil as a secondary fuel.

Table 6.3: Secondary fuel breakdown by survey area (%)

Survey Area	None	Solid fuel	Electricity
Craigy Hill	73	13	8
Antiville	70	14	13
Town Parks	68	15	14

Table 6.4: Type of solid fuel burnt in primary and secondary use

Survey Area	Non-smokeless coal	Smokeless
Craigy Hill	83	17
Antiville	78	22
Town Parks	83	17

Craigy Hill, Antiville and Town Parks all burn more non-smokeless coal than smokeless coal. Quantities of turf, peat and wood were also used as fuel by some households, but as the amount used is so small the emissions are negligible when taken separately. Therefore, for the purpose of this report these sources have been added into the non-smokeless coal figures, the fuel with the most similar emissions factors. It is also worth noting that all types of smokeless fuels (anthracite, Phurnacite, Burnglow etc) have been aggregated together as solid smokeless fuel.

### 6.3 EMISSION FACTORS USED IN THE MODELLING

The  $SO_2$  and  $PM_{10}$  emissions arising from domestic fuel combustion were taken from the UK emission factor database (www.naei.org.uk). This web site is managed by netcen on behalf of defra. The exception to this is the emission factor for sulphur dioxide from household coal, which has been taken from a CRE study carried out for Belfast City Council. This locally derived emission factor is more representative of fuel burnt in Northern Ireland.

Table 6.5: Emissions arising from domestic fuel combustion

Fuel type	SO <sub>2</sub>	PM <sub>10</sub>	Units
Anthracite	13	3.59	kt/mt fuel burnt
<b>Burning Oil</b>	0.42	0.01	kt/mt fuel burnt
Coal	10*	10	kt/mt fuel burnt
SSF	16	5.6	kt/mt fuel burnt

Source: UK emission factor database (www.naei.org.uk)

SSF = solid smokeless fuel

The emission factors shown in Table 6.5 have been applied to the results of the fuel surveys for each grid (Tables 6.2 - 6.4) to calculate an average  $PM_{10}$  and  $SO_2$  emission arising from each block of housing in the area.

<sup>\* -</sup> emission factor taken from CRE, 1997.

## 7 Detailed modelling

### 7.1 METEOROLOGICAL DATA

Hourly sequential meteorological data for 2002 for Aldergrove was obtained. The meteorological data provided information on wind speed, direction, temperature and the extent of cloud cover for each hour of 2002.

### 7.2 OVERVIEW OF THE MODELLING APPROACH

The dispersion model ADMS 3.1 has been used to predict the  $PM_{10}$  and  $SO_2$  levels in Cookstown District. ADMS is a PC-based model that includes an up-to-date representation of the atmospheric processes that contribute to pollutant dispersion and has been deemed suitable for use in the review and assessment process.

The emissions arising from each survey area have been modelled as volume sources 10m high with emission point at 5m. Emissions have been weighted with both seasonal and diurnal emission patterns. The seasonal pattern was calculated on a degree day basis to weight emissions to the colder periods of the year. Temperature data for each hour was taken from the 2002 Aldergrove meteorological data.

The modelled concentrations have then been added to estimated background concentrations (taken from the netcen NAEI web site <a href="https://www.naei.org.uk">www.naei.org.uk</a>).

### 7.2.1 Model bias

The monitoring site at Rosebrook Avenue, Carrickfergus has been used as a reference site: e.g. model concentrations for Larne have been adjusted using the ratio of the modelled concentration at the Rosebrook Avenue monitoring site and the predicted measured value in 2002. The correction factor at this location was applied to the modelled output from Larne. The purpose of this adjustment was at Carrickfergus was to ensure that the modelled concentrations equalled the measured values at the monitoring site. This same correction is then applied to Larne to correct model bias, in the absence of local monitoring data. Whilst there is therefore an element of uncertainty associated with using a bias correction from a different location, this is still preferable to the uncertainty associated with not correcting the model at all. The same modelling methodology has been used at Carrickfergus to maintain consistency and minimise the uncertainty of the bias correction as much as possible.

#### 7.2.2 Model validation

The calculations have not taken account of:

- Uncertainties in the fuel use survey;
- Uncertainties in how the burning of domestic fuel might change in future years;
- Uncertainty resulting from year to year variations in atmospheric conditions;
- Uncertainty in emission factors (See section 6.3).

The above uncertainties are dealt with as fully as possible but it is important to remember that the modelling depends highly on the accuracy of the fuel use survey, which is a sample survey. It is assumed that the fuel use survey is representative and will remain representative of the fuel use at the time of the objectives. As we are assuming the fuel use profile will remain the same there is no need to correct the fuel use survey to the year of the objective. Predicted future background concentrations have been applied.

Likewise the modelling is taken to be representative of a year of the met conditions modelled but met conditions inevitably are open to year on year variability and this can cause variation in actual concentrations. The modelling is for 2002 as meteorological data and fuel use data are available for this year, but not yet available for the year of the objectives.

Emissions Factors are average emission factors and don't take account , for example natural variation in coal and its sulphur content variability.

### 7.3 RESULTS OF MODELLING

### 7.3.1 Larne

Figure 7.3a shows predicted  $SO_2$  concentrations in the Larne area. The model predicts that the 99.9 percentile of the 15 minute mean  $SO_2$  concentration will not be exceeded.

Figure 7.3b shows the predicted  $PM_{10}$  concentrations in the Larne area. The model predicts that the 90.41 percentile of 24 hour  $PM_{10}$  concentrations in 2004 will not be exceeded in some parts of this area. It has been assumed that domestic fuel burning in the area will not change between when the survey was carried out and 2004/5

Figure 7.3a: 99.9 percentile 15 minute mean  $SO_2$  concentrations for the Craigy Hill, Antiville and Town Parks grid areas (modelled as one larger grid, model results corrected for bias using monitoring data from Carrickfergus)

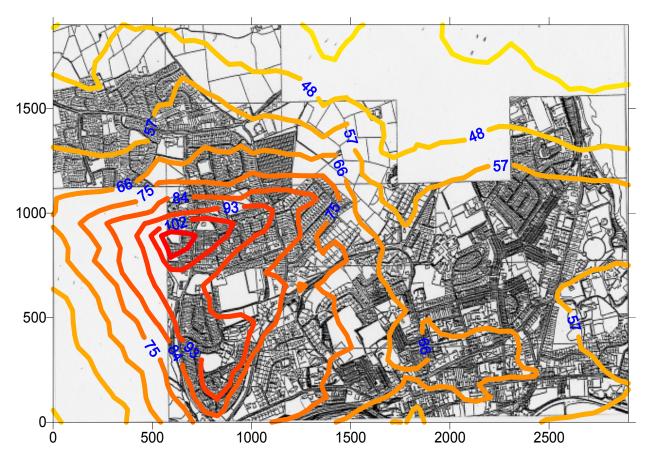

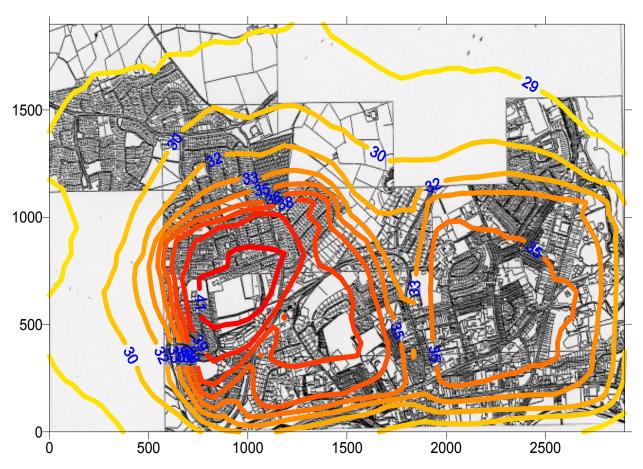

Figure 7.3b: Predicted 90.4 percentile daily mean  $PM_{10}$  concentrations for the Craigy Hill, Antiville and Town Parks grid areas (modelled as one larger grid, model results corrected for bias using monitoring data from Carrickfergus)

## 7.4 SUMMARY OF THE LIKELIHOOD OF EXCEEDING THE OBJECTIVES FOR SO<sub>2</sub>

Detailed modelling using ADMS version 3.1 has been undertaken at three locations where domestic fuel burning is common. The modelling (corrected for bias) predicts that exceedences of the  $SO_2$  objectives are unlikely.

## 7.5 SUMMARY OF THE LIKELIHOOD OF EXCEEDING THE OBJECTIVES FOR PM<sub>10</sub>

Detailed modelling using ADMS version 3.1 has been undertaken at three locations where domestic fuel burning is common. The modelling (corrected for bias) predicts that exceedences of the  $PM_{10}$  objectives are unlikely.

### 7.6 RECOMMENDATIONS

No exceedences of either the  $PM_{10}$  or  $SO_2$  objectives have been predicted. Therefore no further assessment of these sources is required.

This report should now be submitted to defra for review. The Northern Ireland Local Air Quality Management Policy Guidance document (LAQM.PGNI(03)) sets out the timescales for subsequent Review and Assessment activities. Consultation on the stage 2 and stage 3 reports should be undertaken with the general public by March 2004.

When the stage 2/3 assessments are complete, if no AQMA is to be declared the next action is to submit a progress report in April of 2005.

It is recommended that any existing monitoring be continued in order to provide data to prove this modelling in any future rounds of review and assessment.

## Appendix 1

### CARRICKFERGUS AMBIENT AIR MONITORING PROGRAMME

Carrickfergus Borough Council has undertaken automatic ambient air monitoring of  $SO_2$  and  $PM_{10}$  since July 2002. The instrumentation employed uses UV fluorescence for the measurement of  $SO_2$  and the TEOM technique for  $PM_{10}$ , these methods are appropriate for Detailed Assessment under LAQM (LAQM TG(03)). The monitoring station is located in Carrickfergus Town in Rosebrook Avenue. The exact location of the monitoring station is provided below.

**Location of Automatic Monitoring Station in Carrickfergus** 

The data presented here has been provided to **netcen** by Carrickfergus Borough Council as finalised data. Thus no further data scaling or ratification of the data has been undertaken. However, a qualitative review of the data has been completed comparing the trends of the pollutants to nearby AURN monitoring stations. As can be seen in Figures 1 & 2 below, the Carrickfergus dataset broadly follows the same temporal variation as seen at the AURN station at Belfast Centre for  $PM_{10}$  and Belfast Centre and Belfast East for  $SO_2$ . This provides a degree of confidence in the dataset.

The data supplied by Carrickfergus Borough Council, and used in the verification process of the modelling, was uploaded to the **netcen** database and analysis of the data provided the following data summaries. Table 1 provides descriptive statistics of the Carrickfergus data, whilst Table 2 provides comparison against the Air Quality Objective values set down in the Air Quality Regulations (Northern Ireland) 2003.

Table 1: Air Quality Summary Statistics, Carrickfergus 01 July 2002 to 30 June 2003

POLLUTANT	SO <sub>2</sub>	PM <sub>10</sub>
Maximum 15-minute mean	237 μg m <sup>-3</sup>	574 μg m <sup>-3</sup>
Maximum hourly mean	186 μg m <sup>-3</sup>	287 μg m <sup>-3</sup>
Maximum running 24-hour mean	57 μg m <sup>-3</sup>	59 μg m <sup>-3</sup>
Maximum daily mean	52 μg m <sup>-3</sup>	56 μg m <sup>-3</sup>
Average	9 μg m <sup>-3</sup>	20 μg m <sup>-3</sup>
Data capture	88.6 %	78.2 %

Table 2: Air Quality Exceedence Statistics, Carrickfergus 01 July 2002 to 30 June 2003

<u> </u>			
Pollutant	Air Quality Regulations (Northern Ireland) 2003	Exceedences	Days
Sulphur Dioxide	15-minute mean >266 µg m <sup>-3</sup>	0	0
Sulphur Dioxide	Hourly mean > 350 µg m <sup>-3</sup>	0	0
Sulphur Dioxide	Daily mean > 125 µg m <sup>-3</sup>	0	0
PM <sub>10</sub> Particulate Matter (Grav)	Daily mean > 50 μg m <sup>-3</sup>	17	17
PM <sub>10</sub> Particulate Matter (Grav)	Annual mean > 40 μg m <sup>-3</sup>	0	-

Note: A factor of 1.3 has been used to correct TEOM  $PM_{10}$  to gravimetric equivalent  $PM_{10}$ 

Figure 1: PM<sub>10</sub> Hourly Mean Data for 1 July 2002 to 30 June 2003
